**INTRODUCTION**

Lupus erythematosus (LE) is a chronic inflammatory disease with a broad spectrum of cutaneous and systemic manifestations. Skin involvement includes a variety of LE specific lesions subdivided into 3 major categories – chronic cutaneous LE (CCLE), subacute cutaneous LE (SCLE) and acute cutaneous LE (ACLE) – based on clinical and histopathologic examination\textsuperscript{1}.

Patients presenting with SCLE constitute 7\%–27\% of LE cases. These type of lesions are mostly seen in females (ratio 1:4) of caucasian race (>85\%) and are clinically characterized by nonscarring erythematous papulosquamous and/or annular skin lesions with a symmetrical distribution typically located in sun-exposed areas\textsuperscript{2}. Approximately 50\% of patients with SCLE fulfil the American College of Rheumatology classification criteria for Systemic Lupus Erythematosus (SLE), but only 10–15\% will develop severe clinical manifestations of SLE\textsuperscript{3}.

Neonatal LE, with or without congenital heart-block, is also a rare condition seen in 1\% of Lupus women who have anti-Ro and/or La antibodies, regardless of their symptoms\textsuperscript{4}.

**CASE REPORT**

This case refers to a 27 year-old black woman, smoker of 5 cigarettes per day, with a background history of SCLE, diagnosed after a skin biopsy at the age of 20 (Figure 1), and three uncomplicated pregnancies. Seven weeks after her third pregnancy she presented to our clinic with a 4-month history of progressive and widespread erythematous lesions in a photodistribution, mouth ulcers, alopecia, persistent migraines and depression. Her newborn son had a hyperpigmented skin macule, in remission, on his right cheek (Figure 2). Her two other children also had the same type of lesions when they were born. Fetal echocardiograms of all pregnancies were normal. Examination of the patient revealed scaly erythematous macules and annu-

FIGURE 3. Exuberant skin lesions in the patient’s lower and upper limbs and face: Hyperpigmented and scaly erythematosus annular plaques

Severe SCLE associated with an active SLE in black people is an infrequent event. It is known that Lupus disease activity may flare during pregnancy or puerperium and more often in African-Americans and current smokers\(^5\). These facts can substantiate the spectrum of manifestations seen in this patient.

The authors draw attention for the severity and exuberance of the skin involvement in a SLE patient, which is an uncommon presentation in the rheumatology outpatient setting. In addition, they highlight the occurrence of neonatal LE, a very rare condition present all this patient’s newborns.

DISCUSSION/CONCLUSION

Severe SCLE associated with an active SLE in black people is an infrequent event. It is known that Lupus disease activity may flare during pregnancy or puerperium and more often in African-Americans and current smokers\(^5\). These facts can substantiate the spectrum of manifestations seen in this patient.

The authors draw attention for the severity and exuberance of the skin involvement in a SLE patient, which is an uncommon presentation in the rheumatology outpatient setting. In addition, they highlight the occurrence of neonatal LE, a very rare condition present all this patient’s newborns.
